Hybridomas were made from the spleen of a transgenic sibling of the mice whose FACS profile is shown in Figure 3; this mouse is T57 in Table II. After fusion the cells were plated very dilute and only wells that microscopically showed a single clone were further analyzed. [G],[M], low level γ , μ ; ([λ]), λ 1 protein secreted.

* ELISA of the hybridoma secretions showed λ (l), κ and λ (d), κ (k), μ (M), and γ (G) proteins. These were assayed as soon as cell clones were visible in the wells.

† Presence of the γ 2 transgene was determined by Southern blot.

§ Rearrangement of endogenous κ genes was determined from Southern blots of Bam HI-digested DNA probed first with a C κ probe and after stripping reprobed with a 5' of J κ 1 probe ($\times 2.1$; reference 7). \neg Only germline κ genes were seen; del, κ genes (or chromosome deleted); re, rearranged; gl, germline.

|| Rearrangement of endogenous λ genes was determined from Southern blots of Eco R1-digested DNA probed with a V λ 2 probe that crosshybridizes with V λ 1 (40). V λ 1J₁, V λ 1J₃, and V λ 2J₂ rearrangements result in 7.8-, 3.1-, and 6.5-kb fragments, respectively; \neg endogenous λ genes are in germline configuration.

¶ Rearrangement of endogenous H genes was determined from Southern blots of DNA digested with Bam HI and separately with Eco R1 and probed sequentially with 5'DH and JH4. gl, germline (unrearranged) H genes are present. In cases in which no rearrangements are seen, we do not know if both alleles were unrearranged, or the other allele was lost in the hybridoma, or the other allele was a VDJ rearrangement that overlaps with the restriction fragments of the fusing line, Ag8.653. DJ, rearrangement seen with the JH4 probe, and one to five fragments present that hybridize with 5'DH. The fusing line does not retain DNA hybridizing with 5'DH. VDJ, rearranged band seen with J4 probe, but no hybridization with the 5'D probe. Hybridomas indicated to be VDJ/VDJ show two rearranged JH4 bands. DJ/VDJ, two rearranged bands with JH4, one to five bands hybridizing with 5'DH and production of H chains. del, deletion, no evidence of H genes except in most cases the genes of the fusing line are present.

** These wells were originally secreting λ and later became negative, apparently because of loss of the transgenes.

†† No rearrangement visible in Southern blot, but κ mRNA seen in Northern blot.
